## NOVEL COMPOUNDS

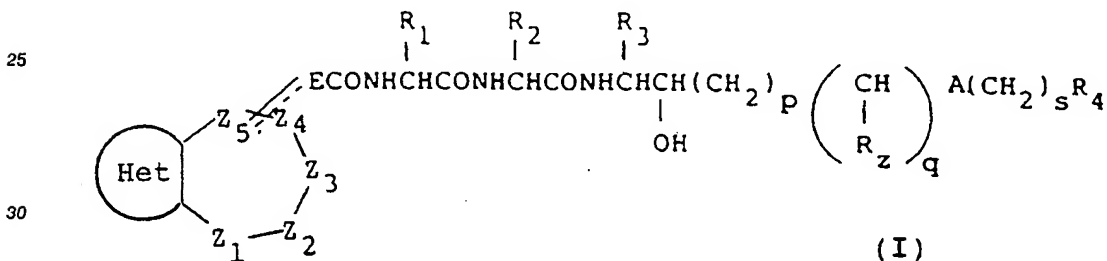

The invention relates to novel compounds having pharmacological activity, to processes for their preparation, to pharmaceutical preparations containing them and to their use in medicine.

Renin is a natural enzyme, disorders in relation to which are implicated in many cases of hypertension. It is released into the blood from the kidney, and cleaves from a blood glycoprotein a decapeptide known as angiotensin-I. Circulating angiotensin-I is cleaved in plasma, and in lung, kidney and other tissues to an octapeptide, angiotensin-II, which raises blood pressure both directly by causing arteriolar constriction and indirectly by stimulating release of the sodium-retaining hormone aldosterone from the adrenal gland and thus causing a rise in extracellular fluid volume. The latter effect is caused by angiotensin-II itself or a heptapeptide cleavage product angiotensin-III.

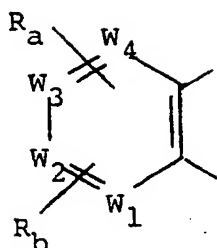

Inhibitors of renin have been described as useful in the treatment of hypertension.

A group of compounds has now been discovered, which inhibit the enzyme renin and therefore have potential blood pressure lowering activity, useful in the treatment of hypertension. Compounds having an associated mechanism of action have also been described as possessing anti-retroviral activity and the present compounds may therefore be of potential use in the treatment of diseases caused by retroviruses including human immunodeficiency virus (HIV-1 and 2) and HTLV I and II. They may also be of potential use in the treatment of other cardiovascular disorders, such as congestive heart failure, and have beneficial effects on learning and memory and mood elevation activity, of potential use in the treatment of CNS disorders such as Alzheimer's disease and depression; they may also be of potential use in the treatment of glaucoma.

15 methods analogous to those used in peptide synthesis, may be employed.

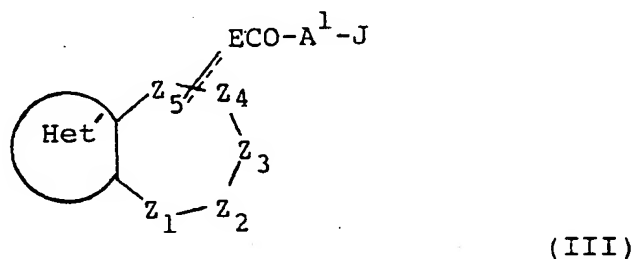

The coupling reactions may be effected by, for example, activating the reacting carboxyl group of the acid of formula (II) or amino acid, and reacting this with the amino group of the substrate unit. Details of suitable, optional activating and protecting (masking) groups and of suitable reaction conditions (for the coupling reactions and for the introduction and removal of protecting groups) giving, preferably, the

20 minimum of racemisation, may be found in the above-referenced literature.

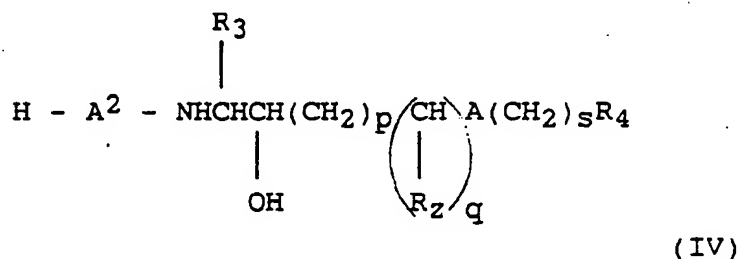

It will be appreciated that, when A is other than -CONH- or -COO-, the C-terminus group is other than an amino acid, in which case the coupling is carried out with an appropriate other precursor, as described in the aforementioned literature -references 2., 5., 6. and 7.

Accordingly, the present invention further provides a process for the preparation of a compound of

25 formula (I) or a pharmaceutically acceptable salt thereof which comprises reacting a reagent of the formula (III):

40 wherein Het' is Het as defined but wherein  $R_a$ ,  $R_b$  and  $R_c$  are  $R_a'$ ,  $R_b'$  and  $R_c'$ , which are  $R_a$ ,  $R_b$  and  $R_c$  respectively or groups or atoms convertible thereto;  $A^1$  is absent or represents an appropriate amino acid or dipeptide unit; J is OH or a leaving group; and the remaining variables are as hereinbefore defined; with a reagent of the formula (IV):

55 wherein  $A^2$  is absent or represents an appropriate amino acid or dipeptide unit, such that  $A^1 + A^2$  is -NHCH $R_1$ CONHCH $R_2$ CO-, and the remaining variables are as hereinbefore defined; and thereafter, if

desired or necessary deprotecting (within A<sup>1</sup> or A<sup>2</sup> of the products, and/or converting Z<sub>1</sub>, Z<sub>2</sub>, Z<sub>3</sub>, Z<sub>4</sub> or Z<sub>5</sub> to other Z<sub>1</sub>, Z<sub>2</sub>, Z<sub>3</sub>, Z<sub>4</sub> or Z<sub>5</sub>, R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub> in Het' to R<sub>a</sub>, R<sub>b</sub> and/or R<sub>c</sub> and/or W<sub>1</sub>, W<sub>2</sub>, W<sub>3</sub> or W<sub>4</sub> in Het' when N to NO; and/or forming a pharmaceutically acceptable salt thereof.

Suitable examples of J when a leaving group include halo, such as chloro or bromo, and other suitable groups which are displaceable by an amino nucleophile, such as C<sub>1-6</sub> alkoxy-carbonyloxy.

It is generally preferred, especially when A<sup>1</sup> is not absent, however, that J is OH, and a suitable coupling reagent or dehydrating catalyst is used to effect the reaction, such as N,N-dicyclohexylcarbodiimide and those described in the Descriptions and Examples hereinafter.

Deprotection of A<sup>1</sup> and/or A<sup>2</sup> takes place conventionally, in accordance with the particular protecting group(s) employed.

Pharmaceutically acceptable salts may be formed conventionally.

Z<sub>1</sub>, Z<sub>2</sub>, Z<sub>3</sub>, Z<sub>4</sub> or Z<sub>5</sub> when S or SO may be converted to SO or SO<sub>2</sub> respectively (or S to SO<sub>2</sub>) by conventional oxidation methods, preferably in a non-aqueous solvent, such as a chlorinated hydrocarbon, in the presence of an organic peracid, such as 3-chloroperoxybenzoic acid, or in water in the presence of a soluble strong inorganic oxidant, such as an alkali metal permanganate or with aqueous hydrogen peroxide. A particularly suitable alternative oxidation method involves the use of magnesium monoperoxophthalate, as described in Description 10b) hereinafter.

It will be apparent that compounds of the formula (I) containing a Het' ring wherein the R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub> group is other than R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub> and which is convertible to an R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub> group, are useful novel intermediates. A number of such conversions is possible, not only for the final product compounds of formula (I) when R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub> are other than R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub>, but also within R<sub>a</sub>/R<sub>b</sub>/R<sub>c</sub>, and also for their intermediates as follows:

- (i) an R<sub>a</sub>/R<sub>b</sub> nitro substituent is convertible to an amino substituent by reduction;
- (ii) a C<sub>1-7</sub> acylamino substituent is convertible to an amino substituent by deacylation;
- (iii) a hydrogen substituent in sub-formula (a) is convertible to a halogen substituent by halogenation;
- (iv) an amino substituent is convertible to a corresponding substituent which is substituted by one or two alkyl groups, by N-alkylation;
- (v) a cyano substituent may be converted to an aminomethyl substituent by reduction;
- (vi) a bromo substituent may be converted to a cyano substituent by reaction with copper(I) cyanide.

Conversions (i) to (vi) are only exemplary and are not exhaustive of the possibilities. It will be appreciated that it is often desirable to carry out these conversions at an earlier stage, in the intermediate acid of formula (II).

In regard to (i), the reduction is carried out with a reagent suitable for reducing nitroanisole to aminocanisole.

In regard to (ii), deacylation is carried out by treatment with a base, such as an alkali metal hydroxide.

In regard to (iv), alkylation is carried out with a corresponding alkylating agent such as the chloride or bromide under conventional conditions.

In regard to (v), the reduction takes place by reaction with sodium borohydride/cobalt chloride or platinum oxide/hydrogen.

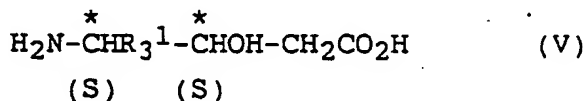

In regard to (vi), the reaction takes place under conventional conditions.

Conversion of W<sub>1</sub>, W<sub>2</sub>, W<sub>3</sub> or W<sub>4</sub> when N to NO may be achieved by similar oxidation methods to those used for Z<sub>1</sub>, Z<sub>2</sub>, Z<sub>3</sub>, Z<sub>4</sub> or Z<sub>5</sub> when S or SO to SO or SO<sub>2</sub>, such as using 3-chloroperoxybenzoic acid. Selective oxidation may be achieved by an appropriate choice of oxidising agent and conditions.

Compounds of the general formulae (II) and (III) may themselves be prepared by standard techniques analogous to those described above.

The acids of formula (II) are either known compounds or are prepared by analogous methods to these and for structurally similar known compounds.

The preparation of the amino acid of formula (V):

is described in J. Med. Chem 1985, 28, 1779-1790.

As regards the appropriate corresponding intermediates to those of formula (V), including those wherein A is other than -CONH-, reference is hereby made to the literature references 2. to 7. listed hereinbefore.

It will be appreciated that protected forms of compounds of the present invention are novel inter-

mediates and form an aspect of the invention.

Particularly suitable methods of preparation of the compounds of the present invention are as described in the Descriptions and Examples hereinafter. The couplings may be carried out sequentially beginning by coupling the acid of formula (II) with, for example, phenylalanine or 1-naphthylalanine, followed by coupling  
 5 with Y, for example, leucine or histidine, and finally, coupling with the amino acid of formula (V). In a preferred aspect, however, either the acid of formula (II) is coupled with a tripeptide unit formed between the amino acid of formula (V); leucine, histidine or other R<sub>2</sub> containing amino acid; and phenylalanine or naphthylalanine; or alternatively the acid of formula (II) is coupled with phenylalanine or naphthylalanine and this is coupled with a dipeptide unit formed between the R<sub>2</sub> containing amino acid and the amino acid of  
 10 formula (V).

As mentioned previously the compounds of the invention have been found to be renin inhibitors, and therefore they are of potential use in the treatment of hypertension. They may also be of potential use in the other diseases and disorders hereinbefore referred to.

The present invention also provides a pharmaceutical composition which comprises a compound of  
 15 formula (I) or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable carrier. In particular, the present invention provides an anti-hypertensive pharmaceutical composition which comprises an anti-hypertensive effective amount of a compound of formula (I) or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable carrier.

The compositions are preferably adapted for oral administration. However, they may be adapted for  
 20 other modes of administration, for example parenteral administration for patients suffering from heart failure. Other alternative modes of administration include sublingual or transdermal administration, or for example, eye-drop compositions, for the treatment of glaucoma.

The compositions may be in the form of tablets, capsules, powders, granules, lozenges, suppositories, reconstitutable powders, or liquid preparations, such as oral or sterile parenteral solutions or suspensions.

25 In order to obtain consistency of administration it is preferred that a composition of the invention is in the form of a unit dose.

Unit dose presentation forms for oral administration may be tablets and capsules and may contain conventional excipients such as binding agents, for example syrup, acacia, gelatin, sorbitol, tragacanth, or polyvinylpyrrolidone; fillers, for example lactose, sugar, maize-starch, calcium phosphate, sorbitol or glycine;  
 30 tableting lubricants, for example magnesium stearate; disintegrants, for example starch, polyvinylpyrrolidone, sodium starch glycollate or microcrystalline cellulose; or pharmaceutically acceptable wetting agents such as sodium lauryl sulphate.

The solid oral compositions may be prepared by conventional methods of blending, filling or tableting. Repeated blending operations may be used to distribute the active agent throughout those compositions  
 35 employing large quantities of fillers. Such operations are of course conventional in the art. The tablets may be coated according to methods well known in normal pharmaceutical practice, in particular with an enteric coating.

Oral liquid preparations may be in the form of, for example, emulsions, syrups, or elixirs, or may be presented as a dry product for reconstitution with water or other suitable vehicle before use. Such liquid  
 40 preparations may contain conventional additives such as suspending agents, for example sorbitol, syrup, methyl cellulose, gelatin, hydroxyethylcellulose, carboxymethylcellulose, aluminium stearate gel, hydrogenated edible fats; emulsifying agents, for example lecithin, sorbitan monooleate, or acacia; non-aqueous vehicles (which may include edible oils), for example almond oil, fractionated coconut oil, oily esters such as esters of glycerine, propylene glycol, or ethyl alcohol; preservatives, for example methyl or propyl p-  
 45 hydroxybenzoate or sorbic acid; and if desired conventional flavouring or colouring agents.

For parenteral administration, fluid unit dosage forms are prepared utilizing the compound and a sterile vehicle, and, depending on the concentration used, can be either suspended or dissolved in the vehicle. In preparing solutions the compound can be dissolved in water for injection and filter sterilized before filling into a suitable vial or ampoule and sealing. Advantageously, adjuvants such as a local anaesthetic, a  
 50 preservative and buffering agents can be dissolved in the vehicle. To enhance the stability, the composition can be frozen after filling into the vial and the water removed under vacuum. Parenteral suspensions are prepared in substantially the same manner, except that the compound is suspended in the vehicle instead of being dissolved, and sterilization cannot be accomplished by filtration. The compound can be sterilized by exposure to ethylene oxide before suspending in the sterile vehicle. Advantageously, a surfactant or  
 55 wetting agent is included in the composition to facilitate uniform distribution of the compound.

For transdermal administration, formulations suitable for topical use may be employed, optionally containing penetration enhancers.

The compositions may contain from 0.1% to 99% by weight, preferably from 10-60% by weight, of the

active material, depending on the method of administration.

The present invention further provides a method of prophylaxis or treatment of hypertension in mammals including man, which comprises administering to the suffering mammal an anti-hypertensively effective amount of a compound of formula (I) or a pharmaceutically acceptable salt thereof.

5 An effective amount will depend on the relative efficacy of the compounds of the present invention, the severity of the hypertension being treated and the weight of the sufferer. However, a unit dose form of a composition of the invention may contain from 0.1 to 500 mg of a compound of the invention and more usually from 1 to 100 mg, for example 2 to 50 mg such as 2, 3, 4, 5, 10, 20 or 30mg. Such compositions may be administered from 1 to 6 times a day, more usually from 2 to 4 times a day, in a manner such that  
10 the daily dose is from 1 to 1000mg for a 70 kg human adult and more particularly from 5 to 500 mg.

No toxicological effects are indicated at the aforementioned dosage ranges.

The present invention further provides a compound of formula (I) or a pharmaceutically acceptable salt thereof for use in the treatment or prophylaxis of hypertension.

## Description 1

## 2,3-Dihydrofuro[3,2-b]pyridine-3-acetic acid

10% Aqueous sodium hydroxide (0.7ml) was added dropwise to a stirred solution of ethyl 2,3-dihydrofuro[3,2-b]pyridine-3-acetate \* (0.32g) in ethanol (5ml) at 0 °C, and the resultant mixture stirred at room temperature for 18h. Water (50ml) was added and the aqueous solution washed with chloroform. The aqueous layer was neutralised with 10% aqueous citric acid and evaporated in vacuo. The residue was triturated with chloroform and filtered and the filtrate was evaporated in vacuo to afford the title compound (0.17g) as a white solid.

Description 2(a) Methyl 2,3-dihydro-3-oxo-4H-pyrido[3,2-b]-1,4-oxazine-4-propanoate

5

Methyl acrylate (0.18ml) was added dropwise to a stirred mixture of 2,3-dihydro-3-oxo-4H-pyrido[3,2-b]-1,4-oxazine (0.50g) and anhydrous potassium carbonate (0.41g) in dry dimethylformamide (DMF) (5ml). The reaction mixture was stirred at room temperature for 66h, poured into water and extracted with chloroform (3x100ml). Combined extracts were dried (Na<sub>2</sub>SO<sub>4</sub>) and the solvent removed in vacuo. The crude product  
 10 was purified by chromatography on silica gel using ethyl acetate/petroleum ether (b.p. 60-80 °C) (0-30% ethyl acetate, gradient) to afford the title compound (0.48g) as a white solid.  
 NMR (δ) (CDCl<sub>3</sub>): 2.75(2H,t), 3.65(3H,s), 4.45(2H,t), 4.7(2H,s), 6.9(1H,dd), 7.2(1H,dd), 8.0(1H,dd).

15 (b) 2,3-Dihydro-3-oxo-4H-pyrido[3,2-b]-1,4-oxazine-4-propanoic acid

10% Aqueous sodium hydroxide (0.56ml) was added to a chilled, stirred solution of methyl 2,3-dihydro-3-oxo-4 H -pyrido[3,2-b]-1,4-oxazine-4-propanoate (0.47g) in methanol (5ml) and the resultant mixture stirred at room temperature for 21h. Solvents were evaporated in vacuo and the residue dissolved in water  
 20 and adjusted to neutrality with 2M hydrochloric acid. The solution was freeze-dried and the residue triturated with methanol/dichloromethane (1:5 mixture). Filtration and evaporation of the filtrate afforded the title compound (0.40g) as a white solid.

Biological Data

In vitro human renin inhibition

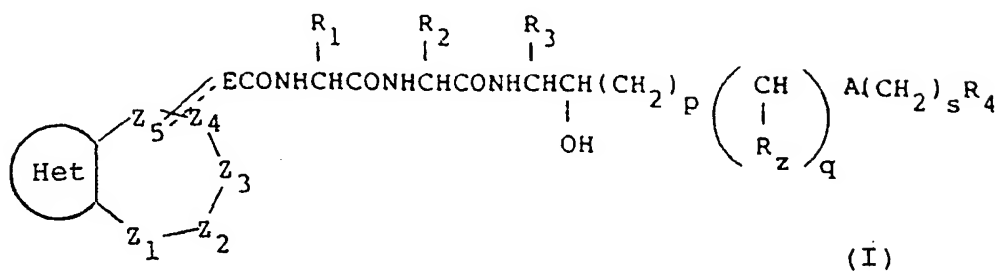

Renin inhibitory activity was estimated as the percentage change in renin activity in human plasma in the presence and absence of compound. The source of plasma was blood taken from healthy volunteers. Renin activity was defined by the difference in angiotensin I levels between two halves of a sample, one incubated at 37° and the other at 4° for 2 h. Angiotensin I levels were measured using a <sup>125</sup>I- angiotensin I radioimmunoassay kit (NEN/Dupont, Stevenage). Results were calculated as the mean of at least two, duplicate determinations and IC<sub>50</sub> values were calculated by linear regression analysis of at least three

concentrations of compound.  
The results were as follows:

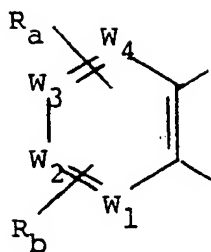

Compound	IC <sub>50</sub> (n-m)
E2	21
E3	26
E4	4
E10	6
E11	12
E14	14
